Econometrics II

WRITTEN EXAMINATION

Monday August 14, 2017

Tools allowed: Pocket calculator

Passing rate: 50% of overall total, which is 100 points. For detailed grading criteria, see the course description.

For the maximum number of points on each problem detailed and clear solutions are required.

Observe: If not indicated otherwise, the error terms ϵ_t in the models are assumed independent and $N(0, \sigma^2)$.

1. (20p) The monthly average values y_t for a particular stock during seven months were:

| Month | y_t |
|-------|-------|
| 1 | 7.2 |
| 2 | 7.0 |
| 3 | 7.4 |
| 4 | 7.3 |
| 5 | 7.2 |
| 6 | 7.1 |
| 7 | 7.2 |

- Would you consider y_t to be stationary? Why/why not?
- Use an appropriate smoothing method to compute a forecast (prognosis) for month number 8. Use the discount factor 0.3 and the whole given series of values for computation of the starting value.
- Compute $\hat{\rho}_1$ and $\hat{\rho}_2$.
- Compute the value of a suitable model-fit measure with respect to your chosen smoothing method.

2. (25p) True or false? Short motivation/comment also needed.
- (a) The Yule-Walker equations are used to obtain autocorrelations for MA processes.
 - (b) Rejection in the unit root test means that we have detected a random walk process.
 - (c) The Hausmann test is used to determine the number of dependent variables in a regression model.
 - (d) A dynamic model for y_t contains at least one lagged y -component.
 - (e) An MA process is always stationary.
 - (f) Doing the second order differencing for a process y_t means that we obtain $y_t - y_{t-1} + y_{t-2}$.
 - (g) The Koyck model and the REM model are both examples of dynamic models.
 - (h) The expectation of y_t in an AR model is equal to the constant term δ .
3. (20p) Consider the following situation: We have three similar companies and for each company we have observed values of three variables Y , X_1 and X_2 . Each variable is observed during the time points $t = 1, \dots, 10$. We want to formulate a model with the X -variables as regressors and Y as the dependent variable.
- (a) Is this a balanced model? Why/why not?
 - (b) Formulate first the pooled OLS regression model with suitable notation and indices.

$$Y_{it} = \dots$$
 - (c) As an alternative we would also like to try a random effects regression model. Formulate also this model.

$$Y_{it} = \dots$$

 In doing this, also explain the difference between the pooled OLS model and the random effects model and how they relate to each other. Especially: How is the error term of the pooled OLS model related to the error term of the random effects model?
 - (d) The Hausmann test is often used to choose between the fixed effects model and the random effects model and technically it is a test about a specific property of the error terms in the random effects model. Which property?

4. (20p) Below we have a model, which is essentially a regression model, but here we will look at it from a times series model perspective.

$$y_t = 3 - 2t + \epsilon_t,$$

where $t = 0, 1, 2, \dots$, $\epsilon_t \sim N(0, 1)$ and $Cov(\epsilon_t, \epsilon_{t-k}) = \tau(k)$.

- (a) Compute (derive expressions of) $E(y_t)$, $V(y_t)$ and $Cov(y_t, y_{t-k})$
- (b) Why is y_t nonstationary? Is ϵ_t stationary? Why/why not?
- (c) If we apply the method of first difference to this times series, do we obtain stationarity? Why/why not?

5. (15p) From a realization of a stationary time series the following estimators were computed: $\hat{\rho}_1 = 0.8$, $\hat{\rho}_2 = 0.5$ and $\hat{\rho}_3 = 0.4$.

- (a) Which AR-model would you fit to these data? AR(1) or AR(2)?
- (b) Derive estimates for the parameters in your chosen model.
- (c) Compute an estimate for ρ_4 .

Formula sheet, Econometrics II, Spring 2017

Under the simple linear model $y_t = \beta_1 + \beta_2 x_t + u_t$, where $u_t \sim N(0, \sigma^2)$ and given independent pairs of observations $(y_1, x_1), \dots, (y_n, x_n)$, the OLS (and ML) estimators are:

$$\begin{aligned}\hat{\beta}_1 &= \bar{y} - \hat{\beta}_2 \bar{x} \\ \hat{\beta}_2 &= \frac{\sum (x_t - \bar{x})(y_t - \bar{y})}{\sum (x_t - \bar{x})^2} \\ \hat{\sigma}^2 &= \frac{RSS}{n-2} = \frac{\sum (y_t - \hat{y}_t)^2}{n-2}\end{aligned}$$

where $\hat{y}_t = \hat{\beta}_1 + \hat{\beta}_2 x_t$ and where $E(\hat{\beta}_1) = \beta_1$, $E(\hat{\beta}_2) = \beta_2$ and $E(\hat{\sigma}^2) = \sigma^2$

Comparing an "old" model with a "new" (larger):

$$\begin{aligned}F &= \frac{(ESS_{new} - ESS_{old})/\text{number of new regressors}}{RSS_{new}/(n - \text{number of parameters in the new model})} \\ &= \frac{(R^2_{new} - R^2_{old})/\text{number of new regressors}}{(1 - R^2_{new})/(n - \text{number of parameters in the new model})}\end{aligned}$$

Comparing an "unrestricted" model with a "restricted":

$$F = \frac{(RSS_R - RSS_{UR})/m}{RSS_{UR}/(n-k)} = \frac{(R^2_{UR} - R^2_R)/m}{(1 - R^2_{UR})/(n-k)}$$

where m is the number of linear constraints and k is the number of parameters in the unrestricted model.

Dynamic models: $y_t = \alpha_0 + \alpha_1 x_t + \alpha_2 y_{t-1} + v_t$

Koyck: $y_t = \alpha(1-\lambda) + \beta_0 x_t + \lambda y_{t-1} + v_t$

Adaptive expectations: $y_t = \gamma \beta_0 + \gamma \beta_1 x_t + (1-\gamma) y_{t-1} + (u_t - (1-\gamma) u_{t-1})$

Partial adjustment: $y_t = \delta \beta_0 + \delta \beta_1 x_t + (1-\delta) y_{t-1} + \delta u_t$

The Durbin-Watson d statistic:

$$d = \frac{\sum_{t=2}^n (\hat{u}_t - \hat{u}_{t-1})^2}{\sum_{t=1}^n \hat{u}_t^2}$$

The Durbin h statistic:

$$h = \hat{\rho} \sqrt{\frac{n}{1 - n [\hat{V}(\hat{\alpha}_2)]}} \approx N(0, 1), \text{ if } \rho = 0$$

$$MSE = \frac{1}{n} \sum_{t=1}^n [\epsilon_t(1)]^2 = \frac{1}{n} \sum_{t=1}^n [y_t - \hat{y}_t(t-1)]^2$$

Autocorrelation function:

$$\rho_k = \frac{Cov(y_t, y_{t+k})}{V(y_t)}, \quad k = 0, 1, 2, \dots$$

Sample correlation function:

$$\hat{\rho}_k = \frac{\sum_{t=1}^{n-k} (y_t - \bar{y})(y_{t+k} - \bar{y})}{\sum_{t=1}^{n-k} (y_t - \bar{y})^2}, \quad k = 0, 1, 2, \dots$$

Simple moving average:

$$M_T = \frac{1}{N} \sum_{t=T-N+1}^T y_t$$

First-order exponential smoothing:

$$\tilde{y}_T = \lambda y_T + (1-\lambda) \tilde{y}_{T-1}$$

Second-order exponential smoothing:

$$\tilde{y}_T^{(2)} = \lambda \tilde{y}_T^{(1)} + (1-\lambda) \tilde{y}_{T-1}^{(2)}$$

where $\tilde{y}_0^{(2)} = \tilde{y}_1^{(1)}$

Holt's method:

$$\begin{aligned} L_t &= \alpha y_t + (1-\alpha)(L_{t-1} + T_{t-1}) \\ T_t &= \gamma(L_t - L_{t-1}) + (1-\gamma)T_{t-1} \end{aligned}$$

$$\tilde{y}_{T+\tau}^{(1)}(T) = L_T + \tau T_T, \quad \tau = 1, 2, \dots$$

Forecast under a constant process:

$$\hat{y}_{T+\tau}(T) = \bar{y}_T \quad \tau = 1, 2, \dots$$

Forecast under a linear trend:

$$\hat{y}_{T+\tau}(T) = \hat{y}_T + \hat{\beta}_{1,T}\tau,$$

where $\hat{y}_T = \hat{\beta}_{0,T} + \hat{\beta}_{1,T}T = 2\hat{y}_T^{(1)} - \hat{y}_T^{(2)}$

For white noise:

$$\hat{\rho}_k \approx N(0, 1/n), k = 1, 2, \dots$$

The Q statistic:

$$Q = n \sum_{k=1}^K \hat{\rho}_k^2 \approx \chi^2(K)$$

The Ljung-Box statistic:

$$Q_{LB} = n(n+2) \sum_{k=1}^K \left(\frac{\hat{\rho}_k^2}{n-k} \right) \approx \chi^2(K)$$

ARMA(p,q):

$$y_t = \delta + \sum_{i=1}^p \phi_i y_{t-i} + \epsilon_t - \sum_{i=1}^q \theta_i \epsilon_{t-i}$$

Stationarity and invertibility conditions for some time series models:

| Model | Stationarity conditions | Invertibility conditions |
|-----------|---|---|
| AR(1) | $ \phi_1 < 1$ | None |
| AR(2) | $\begin{aligned} \phi_1 + \phi_2 &< 1 \\ \phi_2 - \phi_1 &< 1 \\ \phi_2 &< 1 \end{aligned}$ | None |
| MA(1) | None | $\theta_1 < 1$ |
| MA(2) | None | $\begin{aligned} \theta_1 + \theta_2 &< 1 \\ \theta_2 - \theta_1 &< 1 \\ \theta_2 &< 1 \end{aligned}$ |
| ARMA(1,1) | $ \phi_1 < 1$ | $ \theta_1 < 1$ |
| ARMA(2,2) | $\begin{aligned} \phi_1 + \phi_2 &< 1 \\ \phi_2 - \phi_1 &< 1 \\ \phi_2 &< 1 \end{aligned}$ | $\begin{aligned} \theta_1 + \theta_2 &< 1 \\ \theta_2 - \theta_1 &< 1 \\ \theta_2 &< 1 \end{aligned}$ |

The Yule-Walker equations for AR(p):

$$\rho_k = \sum_{j=1}^p \phi_j \rho_{k-j}, \quad k = 1, 2, \dots$$

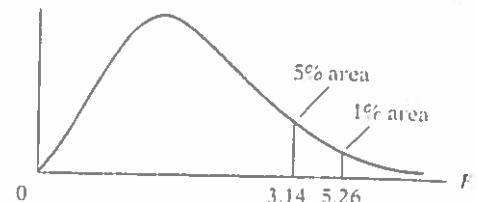

TABLE D-3 Upper Percentage Points of the F Distribution**Example**

$$\Pr(F > 1.59) = 0.25$$

$$\Pr(F > 2.42) = 0.10 \quad \text{for df } N_1 = 10$$

$$\Pr(F > 3.14) = 0.05 \quad \text{and } N_2 = 9$$

$$\Pr(F > 5.26) = 0.01$$

| df for denominator N_2 | Pr | df for numerator N_1 | | | | | | | | | | | |

1

y_t

7.1

7.2

7.3

- 3 4 5 6 7 8

a) Yes, because it seems like that the process goes around its mean value.

OK

b) Since there is both upward and downward trend? I will use the second-order exponential smoothing.

Month y_t

1 7.2

2 7.0

3 7.4

4 7.3

5 7.2

6 7.1

7 7.2

$\lambda = 0.3$

$$\tilde{y}_0 = \bar{y} = 7.2$$

mean
first-order is
enough here

$$\tilde{y}_1^{(1)} = 0.3 y_1 + (1-0.3) \tilde{y}_0 = 0.3 \cdot 7.2 + 0.7 \cdot 7.2 = 7.2$$

$$\tilde{y}_2^{(1)} = 0.3 y_2 + (1-0.3) \tilde{y}_1 = 0.3 \cdot 7.0 + 0.7 \cdot 7.2 = 7.14$$

$$\tilde{y}_3^{(1)} = 0.3 y_3 + (1-0.3) \tilde{y}_2 = 0.3 \cdot 7.4 + 0.7 \cdot 7.14 = 7.12$$

$$\tilde{y}_4^{(1)} = 0.3 y_4 + (1-0.3) \tilde{y}_3 = 0.3 \cdot 7.3 + 0.7 \cdot 7.12 = 7.24$$

$$\tilde{y}_5^{(1)} = 0.3 y_5 + (1-0.3) \tilde{y}_4 = 0.3 \cdot 7.2 + 0.7 \cdot 7.24 = 7.23$$

$$\tilde{y}_6^{(1)} = 0.3 y_6 + (1-0.3) \tilde{y}_5 = 0.3 \cdot 7.1 + 0.7 \cdot 7.23 = 7.19$$

$$\tilde{y}_7^{(1)} = 0.3 y_7 + (1-0.3) \tilde{y}_6 = 0.3 \cdot 7.2 + 0.7 \cdot 7.19 = 7.19$$

Second-order exponential smoothing

$$\tilde{y}_0^{(1)} = \tilde{y}_1^{(1)}$$

$$\tilde{y}_T^{(1)} = \lambda \tilde{y}_T^{(1)} + (1-\lambda) \tilde{y}_{T-1}^{(1)}$$

$$\tilde{y}_1^{(2)} = 0.3 \tilde{y}_1^{(1)} + (1-0.3) \tilde{y}_0^{(2)} = 0.3 \cdot 7.2 + 0.7 \cdot 7.2 = 7.2$$

$$\tilde{y}_2^{(2)} = 0.3 \tilde{y}_2^{(1)} + 0.7 \tilde{y}_1^{(2)} = 0.3 \cdot 7.14 + 0.7 \cdot 7.2 = 7.18$$

$$\tilde{y}_3^{(2)} = 0.3 \tilde{y}_3^{(1)} + 0.7 \tilde{y}_2^{(2)} = 0.3 \cdot 7.21 + 0.7 \cdot 7.18 = 7.19$$

$$\tilde{y}_4^{(2)} = 0.3 \tilde{y}_4^{(1)} + 0.7 \tilde{y}_3^{(2)} = 0.3 \cdot 7.24 + 0.7 \cdot 7.19 = 7.21$$

$$\tilde{y}_5^{(2)} = 0.3 \tilde{y}_5^{(1)} + 0.7 \tilde{y}_4^{(2)} = 0.3 \cdot 7.23 + 0.7 \cdot 7.21 = 7.22$$

$$\tilde{y}_6^{(2)} = 0.3 \tilde{y}_6^{(1)} + 0.7 \tilde{y}_5^{(2)} = 0.3 \cdot 7.19 + 0.7 \cdot 7.22 = 7.21$$

$$\tilde{y}_7^{(2)} = 0.3 \tilde{y}_7^{(1)} + 0.7 \tilde{y}_6^{(2)} = 0.3 \cdot 7.19 + 0.7 \cdot 7.21 = 7.20$$

Forecast under a linear trend $\hat{y}_{T+\tau}(T) = \hat{y}_T + \hat{\beta}_1 \cdot \tau$

$$\hat{\beta}_1 = \frac{\sum (x_t - \bar{x})(y_t - \bar{y})}{\sum (x_t - \bar{x})^2} = -\frac{0.11}{28} + 0 \Rightarrow \hat{\beta}_1 = 0$$

$$x_t = \text{month} \quad y_t = (x_t - \bar{x})(x_t - \bar{x})^2 \quad (x_t - \bar{x})(y_t - \bar{y})$$

| | | | | |
|---|-----|----|---|------|
| 1 | 7.2 | -3 | 0 | 0 |

| 7 | 7.2 | 3 | 9 | 0 |

$$\bar{x} = 4 \quad \bar{y} = 7.2 \quad \sum x_t = 28 \quad \sum y_t = 0$$

Computation of $\hat{\gamma}_T^{(2)} = 2\tilde{y}_T^{(1)} - \tilde{y}_T^{(2)}$

$$\hat{\gamma}_1^{(2)} = 2 \cdot \tilde{y}_1^{(1)} - \tilde{y}_1^{(2)} = 2 \cdot 7.2 - 7.2 = 7.2$$

$$\hat{\gamma}_2^{(2)} = 2 \cdot \tilde{y}_2^{(1)} - \tilde{y}_2^{(2)} = 2 \cdot 7.14 - 7.18 = 7.1$$

$$\hat{\gamma}_3^{(2)} = 2 \cdot \tilde{y}_3^{(1)} - \tilde{y}_3^{(2)} = 2 \cdot 7.21 - 7.19 = 7.25$$

$$\hat{\gamma}_4^{(2)} = 2 \cdot \tilde{y}_4^{(1)} - \tilde{y}_4^{(2)} = 2 \cdot 7.24 - 7.21 = 7.27$$

$$\hat{\gamma}_5^{(2)} = 2 \cdot \tilde{y}_5^{(1)} - \tilde{y}_5^{(2)} = 2 \cdot 7.23 - 7.22 = 7.24$$

$$\hat{\gamma}_6^{(2)} = 2 \cdot \tilde{y}_6^{(1)} - \tilde{y}_6^{(2)} = 2 \cdot 7.19 - 7.20 = 7.17$$

$$\hat{\gamma}_7^{(2)} = 2 \cdot \tilde{y}_7^{(1)} - \tilde{y}_7^{(2)} = 2 \cdot 7.19 - 7.20 = 7.18$$

SU, DEPARTMENT OF STATISTICS

Room: Brunnvikssalen Anonymous code: ETO-0014 Sheet number: 2

Forecast for month 8.

$$\hat{y}_{t+1}(7) = \hat{y}_7 + 0.1 = \hat{y}_7 = 7.18$$

- d) For the second-order exponential smoothing, a suitable model fit measure is. MSE (mean squared error)

$$\begin{aligned} \text{MSE} &= \frac{1}{n} \sum_{t=1}^n [e_t(1)]^2 = \frac{1}{n} [(7.2 - 7.18)^2 + (7.0 - 7.18)^2 + \dots] \\ &= \frac{1}{7} [0.0103] = 0.0058 \end{aligned}$$

OK

e) $\hat{\rho}_1$ and $\hat{\rho}_2$

Sample autocorrelation function

$$\hat{\rho}_k = \frac{\sum_{t=1}^{n-k} (y_t - \bar{y})(y_{t+k} - \bar{y})}{\sum_{t=1}^{n-k} (y_t - \bar{y})^2} \quad k=1$$

$$\begin{aligned} \hat{\rho}_1 &= \frac{\sum_{t=1}^5 (y_t - \bar{y})(y_{t+1} - \bar{y})}{\sum_{t=1}^5 (y_t - \bar{y})^2} = \frac{(7.2 - 7.18)(7.0 - 7.18) + (7.0 - 7.18)(7.4 - 7.18) + \dots}{(7.2 - 7.18)^2 + (7.0 - 7.18)^2 + (7.4 - 7.18)^2 + \dots} \\ &= \frac{-0.02}{0.1} = -0.2 \end{aligned}$$

$$\begin{aligned} \hat{\rho}_2 &= \frac{\sum_{t=1}^5 (y_t - \bar{y})(y_{t+2} - \bar{y})}{\sum_{t=1}^5 (y_t - \bar{y})^2} = \frac{-0.03}{0.09} = -0.33 \end{aligned}$$

OK

116

(2)

a) False.

The Yule-Walker equations are used to obtain autocorrelations for AR-processes.

For example, :

$$P_k = \sum_{i=1}^k \phi_i P_{k-i}, \quad k=1, 2, \dots$$

$$\text{AR}(1) \Rightarrow P_1 = \phi_1 P_0 = \phi_1$$

$$P_2 = \phi_1 P_1 = \phi_1 \phi_1 = \phi_1^2$$

$$P_3 = \phi_1 P_2 = \phi_1 \phi_1^2 = \phi_1^3$$

$$P_k = \phi_1^k$$

$$\text{AR}(2) \quad P_1 = \phi_1 P_0 + \phi_2 P_1 = \phi_1 + \phi_2 P_1$$

$$\Rightarrow P_1 = \frac{\phi_1}{1 - \phi_2}$$

$$P_2 = \phi_1 P_1 + \phi_2 P_0 = \phi_1 P_1 + \phi_2$$

OK

b) False

For unit root test, we start from the random walk process.

$$y_t = \rho y_{t-1} + u_t \quad \text{if } \rho = 1, \text{ the process is nonstationary.}$$

We have a unit problem. Here, OLS method is not appropriate for estimation. So we transform the equation.

$$y_t - y_{t-1} = (\rho - 1) y_{t-1} + u_t$$

$$\Delta y_t = \underbrace{(\rho - 1) y_{t-1}}_g + u_t \quad \leftarrow \begin{array}{l} \text{we use this equation to test} \\ \text{for stationarity.} \end{array}$$

$$H_0: g = 0 \quad (\rho = 1) \rightarrow \text{the process is not stationary}$$

Therefore, rejection of the unit root test means that we do not have detected a random walk process.

OK

SU, DEPARTMENT OF STATISTICS

Room: Brunnvikssalen Anonymous code: ETO-0014 Sheet number: 3

c) False

The Hausmann test is used to test if there is a serial correlation in REM.

H_0 : No significant difference between FEM (the Fixed-Effect model) and REM (the Random effect model).

H_1 : FEM is preferred due to a serial correlation in REM.

OK

d) True

According to Koyck transformation, the Koyck model is defined as $y_t = \alpha(1-\lambda) + \beta_0 x_t + \lambda y_{t-1} + v_t$,
 $\Rightarrow u_t = \lambda u_{t-1}$

As a realization of Koyck model, there are two other models, such as the adaptive expectations model and the partial (Stock) adjustment model.

Adaptive expectations model: $y_t = \gamma \beta_0 + \gamma \beta_1 x_t + (1-\gamma) y_{t-1} + v_t - (1-\gamma) u_{t-1}$

Partial adjustment model: $y_t = \delta \beta_0 + \delta \beta_1 x_t + (1-\delta) y_{t-1} + \delta u_t$

For Koyck and Adaptive expectations,

$$\text{Cov}(u_t, v_{t-1}) = -\lambda \sigma^2 \text{ for Koyck, } -\gamma \sigma^2 \text{ for Adaptive expectations}$$

$$\text{Cov}(u_t, v_t) = -\lambda \sigma^2 \quad , \quad -\gamma \sigma^2 \quad "$$

On the other hand for the partial adjustment model

$$\text{Cov}(u_t, v_{t-1}) = \text{Cov}(u_{t-1}, v_t) = 0.$$

As we see the formulas for these models, the dynamic models contain at least one lagged y-component

OK

e) True.

For example, a MA(1) process is $y_t = \delta + \theta_1 \varepsilon_{t-1} + \varepsilon_t$, $\varepsilon_t \sim N(0, \sigma^2)$

$$\begin{aligned} E(y_t) &= E(\delta + \theta_1 \varepsilon_{t-1} + \varepsilon_t) \\ &= \delta + \theta_1 E(\varepsilon_{t-1}) + E(\varepsilon_t), \\ &\quad \stackrel{=0}{=} \stackrel{=0}{=} \end{aligned}$$

$E(y_t) = \delta$ \leftarrow constant mean. It does not depend on time.

All pure MA(p) processes are stationary.

OK

f) False

The second order differencing can be written as

$$(1 - B)^2 y_t.$$

$$(1 - B)^2 y_t = (1 - 2B + B^2) y_t = y_t - 2y_{t-1} + y_{t-2}$$

OK

g) False

The Koyck model is an example of dynamic models.

But, the REM is an example of panel data models that take account in both cross-section data and time series data.

OK

h) False

For example, an AR(1) model $\Rightarrow y_t = \delta + \phi_1 y_{t-1} + \varepsilon_t$, $\varepsilon_t \sim N(0, \sigma^2)$

$$\begin{aligned} E(y_t) &= E(\delta + \phi_1 y_{t-1} + \varepsilon_t) \\ &= \delta + \phi_1 E(y_{t-1}) + E(\varepsilon_t) \\ &\quad \stackrel{=0}{=} \stackrel{=0}{=} E(y_{t-1}) \end{aligned}$$

$$(1 - \phi_1) E(y_t) = \delta$$

$$E(y_t) = \frac{\delta}{1 - \phi_1}$$

OK

1/25

SU, DEPARTMENT OF STATISTICS

Room: Brunnikssalen Anonymous code: ETO-0014 Sheet number: 4

3

3 companies, time points $t=1 \dots 10$ $3 \times 3 \times 10 = 90$ obs.

3 variables: X_1, X_2, X_3

- Yes, each company has same quantity of observations for all 3 variables and for all time points ($t=10$). OK
- the pooled OLS regression model

$$Y_{it} = \beta_0 + \beta_1 X_{1, it} + \beta_2 X_{2, it} + u_{it}, \quad u_{it} \sim \text{iid } (0, \sigma^2)$$

All company has same intercept.

OK

- REM (Random effects model)

$$Y_{it} = \beta_0 + \beta_1 X_{1, it} + \beta_2 X_{2, it} + u_{it} \rightarrow u_{it} = \varepsilon_i + \eta_{it}$$

REM treats β_{0i} as a random variable, $\beta_{0i} = \beta_0 + \varepsilon_i$

In this model, each company has its own intercept, ε_i

ε_i is a deviation from the mean value of Y_{it} .

But ε_i is not directly observable.

On the other hand, the Pooled OLS model doesn't allow heterogeneity that may exist among the companies by "lumping" together all observations and forcing all company to have same intercept.

Regarding the error terms, the error term of the Pooled OLS, (u_{it}) can be correlated with the regressors.

This results biased and inconsistent OLS estimators.

The error term of the REM is defined as $u_{it} = \varepsilon_i + \eta_{it}$, differently from the error term of the Pooled OLS.

7

$$\text{Cov}(w_{it}, w_{jt}) = \text{Cov}(\varepsilon_i + u_{it}, \varepsilon_j + u_{jt})$$

$$= E(\varepsilon_i^2) = V(\varepsilon_i) = \sigma^2 \leftarrow \text{positive correlation}$$

The big problem of REM is that there is possibility of a correlation between the error term and the regressors.

OK

a) $E(\varepsilon_i \varepsilon_j) = 0, E(\varepsilon_i u_{it}) = 0, i \neq j$

$$E(u_{it} u_{js}) = E(u_{ij} u_{is}) = E(u_{it} u_{js}) = 0, i \neq j, t \neq s$$

115

$$y_t = 3 - 2t + \varepsilon_t$$

$$t = 0, 1, 2, \dots, T \sim N(0, 1)$$

$$\text{Cov}(\varepsilon_t, \varepsilon_{t+1}) = \text{Cov}(\varepsilon_t, \varepsilon_{t+2}) = \dots$$

$$\begin{aligned} a) E(y_t) &= E(3 - 2t + \varepsilon_t) \\ &= 3 - 2E(t) + E(\varepsilon_t) \\ &= 3 - 2t \quad \text{OK?} \end{aligned}$$

$$t=1 \quad y_1 = 3 - 2 \cdot 1 + \varepsilon_1$$

$$y_2 = 3 - 2 \cdot 2 + \varepsilon_2$$

$$y_3 = 3 - 2 \cdot 3 + \varepsilon_3$$

$$V(y_t) = V(3 - 2t + \sum \varepsilon_t)$$

$$y_t = 3 - 2t + \sum \varepsilon_t$$

$$= \sum V(\varepsilon_t) = t \cdot \sigma^2 \quad \checkmark$$

$$\text{Cov}(y_t, y_{t+k}) = \text{Cov}[(3 - 2t + \varepsilon_t), (3 - 2(t+k) + \varepsilon_{t+k})]$$

$$= \text{Cov}[(3 - 2t + \varepsilon_t), (3 - 2t - 2k + \varepsilon_{t+k})]$$

$$= E(9 - 6t + 6k + 3\varepsilon_t \varepsilon_{t+k} - 6t + 4t^2 - 4tk - 2t \varepsilon_{t+k} + 3\varepsilon_t \varepsilon_{t+k} + 2k \varepsilon_{t+k} + k^2 \varepsilon_{t+k}^2)$$

$$= 9 - 6t + 6k - 6t + 4t^2 - 4tk \quad \checkmark$$

$$= 4t^2 + 12t + 6k - 4tk + 9 \quad \checkmark$$

b) y_t is nonstationary because it does not have constant mean and constant variance over time.

They depend on time.

OK

→ next page

SU, DEPARTMENT OF STATISTICS

Room: Brunnrikssalen Anonymous code: ETO-004 Sheet number: 5

④ b) ε_t is stationary since its mean is zero and the variance of ε_t is 1. It does not depend on time. (variance?)

c) (NO. ✓)

$$(-\beta)y_t = \beta - 2t + \varepsilon_t$$

$$y_t - y_{t-1} = \beta - 2t + \varepsilon_t \quad ?$$

$$y_t = \beta - 2t + y_{t-1} + \varepsilon_t$$

$$E(y_t) = E(\beta - 2t + y_{t-1} + \varepsilon_t)$$

$$E(y_t) = \beta - 2t + E(y_{t-1}) + 0$$

$$E(y_t) = 0$$

$$\begin{aligned} V(y_t) &= V(\beta - 2t + y_{t-1} + \varepsilon_t) \\ &= V(y_{t-1}) + \sum V(\varepsilon_t) \\ &= V(y_{t-1}) + t \cdot \sigma^2 \end{aligned}$$

The variance still depends on time.

16

(5)

$$\hat{\rho}_1 = 0.8 \quad \hat{\rho}_2 = 0.5 \quad \hat{\rho}_3 = 0.4$$

a) I would solve AR(2). According to the Yule-Walker equation the autocorrelations of AR(1) can be computed as below.

$$\rho_k = \phi_1^k.$$

If $\hat{\rho}_1 = 0.8$, it means the parameter in AR(1), ϕ_1 , should be equal to 0.8.

BUT $\hat{\rho}_2 = \phi_1^2 = 0.8^2 = 0.64$. It doesn't match with the estimation of $\hat{\rho}_2 = 0.5$.

OK

b) AR(2) model is written as

$$y_t = s + \phi_1 y_{t-1} + \phi_2 y_{t-2} + \varepsilon_t$$

Yule-Walker equation for the autocorrelation

$$\rho_k = \sum_{j=1}^k \phi_j \rho_{k-j}, \quad k=1, 2, \dots$$

$$\rho = \phi_1 \rho_1 + \phi_2 \rho_2 = \phi_1 + \phi_2 \phi_1 = \frac{\phi_1}{1 - \phi_2}$$

$$\rho_1 = \phi_1 \rho_0 + \phi_2 \rho_1 = \phi_1 \rho_1 + \phi_2$$

$$\hat{\rho}_1 = 0.8 \Rightarrow 0.8 = \frac{\phi_1}{1 - \phi_2} \quad \phi_1 = 0.8(1 - \phi_2)$$

$$\hat{\rho}_1 = 0.5 \Rightarrow 0.5 = \phi_1 + 0.8\phi_1 \quad \phi_1 = 0.5(1 + 0.8)$$

$$0.5 = (0.8 - 0.8\phi_1) 0.8 + \phi_1$$

$$\underline{\phi_2 = -0.39}$$

$$\underline{\phi_1 = 1.112} \quad \text{OK}$$

SU, DEPARTMENT OF STATISTICS

Room: Brunnvikssalen Anonymous code: ETO-0014 Sheet number: 6

c) $P_4 = \phi_1 P_3 + \phi_2 P_2$

$k=4$

$$P = \frac{-0.39 \cdot 0.4 + 1.11 \cdot 0.5}{1.11} = 0.4025 \quad (\text{Själv!})$$

a) y_t

7,0

Ovan är observationerna plotade och utifrån denna ser y_t ut att vara stationär då det bara är små fluktuationer kring väntevärdelet. **OK**

b) För en konstant process kan vi använda 1:order exponential smoothing: $\lambda = 0,3$ $\tilde{y}_0 = \bar{y} = \frac{1}{7} \sum_{t=1}^7 y_t = 7,2$

$$\tilde{y}_T = \lambda y_T + (1-\lambda) \tilde{y}_{T-1}$$

$$\tilde{y}_1 = 0,3 \cdot 7,2 + 0,7 \cdot 7,2 = 7,2$$

Resterande utjämna värden beräknas enligt ovan och redovisar i tabellen.

Forecast under en konstant process ges av:

$$\hat{y}_{T+\tau}(T) = \tilde{y}_T \quad \text{dvs.}$$

$$\hat{y}_8(7) = \tilde{y}_7 \approx 7,194$$

OK

$$c) \hat{\rho}_n = \frac{\sum_{t=1}^{n-w} (y_t - \bar{y})(y_{t+n} - \bar{y})}{\sum_{t=1}^n (y_t - \bar{y})^2}$$

$$\hat{\rho}_1 = \frac{\sum_{t=1}^6 (y_t - \bar{y})(y_{t+1} - \bar{y})}{\sum_{t=1}^6 (y_t - \bar{y})^2}$$

$$= \frac{0 + (-0,2) \cdot 0,2 + 0,2 \cdot 0,1 + 0 + 0,1 + 0}{0^2 + (-0,2)^2 + 0,2^2 + 0,1^2 + 0^2 + (0,1)^2} = \frac{0,02}{0,1} = \underline{0,02}$$

OK

$$\hat{\rho}_2 = \frac{\sum_{t=1}^5 (y_t - \bar{y})(y_{t+2} - \bar{y})}{\sum_{t=1}^5 (y_t - \bar{y})^2}$$

$$= \frac{0 + (-0,2) \cdot 0,1 + 0 + 0,1 \cdot (-0,1) + 0}{0^2 + (-0,2)^2 + 0,2^2 + 0,1^2 + 0^2} = \frac{-0,03}{0,09} = \underline{-0,33}$$

OK

d) Vi kan använda MSE (Mean square error)

som ett mätte på modell fit:

$$MSE = \frac{1}{7} \cdot \sum_{t=1}^7 (y_t - \bar{y}_{t+1})^2 = \frac{1}{7} \cdot 0,1158 = \underline{0,016}$$

18

Uppgift 2

- a) Falskt. Yule-Walkers ekvationerna används för att få autocorrelationerna för en AR-process. **OK**
- b) Falskt. Nullhypotesen är att $\beta = 0$ där $\beta = 1 - \rho$, dvs om $\beta = 0 \Leftrightarrow \rho = 1$ och vi får en random walk process. **OK**
- c) Falskt. Hausmann-testet används för att avgöra om en Fixed-effects-modell är lämpligare än en Random-effects-modell. **OK**
- d) Falskt ✓ En clynamisk modell ges av ~~$y_t = \alpha_0 + \alpha_1 x_t + \alpha_2 y_{t-1} + v_t$~~
 $y_t = \alpha_0 + \alpha_1 x_t + \alpha_2 y_{t-1} + v_t$, dvs bara en lagrad y-term
- e) Sant: Eftersom en MA-process är en variant på en infinite moving average-modell, som alltid är stabil och, gäller detta. **OK**
- f) Falskt : Vi får $y_t - 2y_{t-1} + y_{t-2}$.
OK
- g) Falskt. REN är inte en clynamisk modell, däremot är Roychek det. **OK**
- h) Falskt. För en AR(p) gäller att:
- $$E(y_t) = \mu = \frac{\beta}{1 - \phi_1 - \dots - \phi_p}$$

OK**1/20**

SU, STATISTIK

Skrivsal: Brunnslustalen

Anonymkod: ETO-0020

Blad nr: 3

Uppgift 3

a) Ja, det är en balanserad modell eftersom vi har observerade värden på varje variabel i alla belpunkter

OK

b) $Y_{it} = \beta_0 + \beta_1 X_{1it} + \beta_2 X_{2it} + u_{it}$ $i=1, 2, 3$
 $t=1, 2, \dots, 10$

OK

c)

~~$\hat{Y}_{it} = \beta_0 + \beta_1 X_{1it} + \beta_2 X_{2it} + u_{it}$~~

d) Egenskapen som beskrivs är om feltermerna är okorrelerade med regressorerna. Om de är det genereras RLM inkonsistenta skattningar och FEM är då ett bättre val

OK

14

SU, STATISTIK

Skrivsal: Brunnshusalen

Anonymkod: FTO-0020 Blad nr: 4

$$4. \quad y_t = 3 - 2t + \varepsilon_t \quad t = 0, 1, 2, \dots \quad \varepsilon_t \sim N(0, 1)$$

$$\text{Cov}(\varepsilon_t, \varepsilon_{t-u}) = \Gamma(u)$$

$$a) \quad E(y_t) = E(3 - 2t + \varepsilon_t)$$

$$E(y_t) = 3 - 2t$$

$$V(y_t) = V(3 - 2t + \varepsilon_t)$$

$$= V(3) - V(2t) + V(\varepsilon_t)$$

$$V(y_t) = 1$$

$$\begin{aligned} \text{Cov}(y_t, y_{t-u}) &= \text{Cov}(3 - 2t + \varepsilon_t, 3 - 2(t-u) + \varepsilon_{t-u}) \\ &= \underbrace{-2 \text{Cov}(t, t-u)}_0 + \underbrace{\text{Cov}(\varepsilon_t, \varepsilon_{t-u})}_{\Gamma(u)} \end{aligned}$$

$$\text{Cov}(y_t, y_{t-u}) = \text{Cov}(\varepsilon_t, \varepsilon_{t-u}) = \Gamma(u)$$

OK

b) För att en tidsserie ska vara stationär ska väntevärdet och variansen vara konstanta och kovariansen mellan y_t och y_{t-u} ska vara beroende av laggen och inte tiden. I modellen ovan minskar väntevärdet med tiden men variansen är konstant. Därför är den ej stationär. ε_t är dock stationär eftersom den har väntevärdet 0, variansen 1 och en kovarianc som bara är en funktion av laggen u , vilket anges i uppgiften.

OK

c) Ja, den blir stationär. Om vi tar t i a differensier för vi:

$$y_t - y_{t-1} = 3 - 2t + \varepsilon_t - (3 - 2(t-1) + \varepsilon_{t-1})$$

$$\Delta y_t = 3 - 2t + \varepsilon_t - 3 + 2(t-1) - \varepsilon_{t-1}$$

$$\Delta y_t = -2 + \varepsilon_t - \varepsilon_{t-1}$$

$$E(\Delta y_t) = E(-2 + \varepsilon_t - \varepsilon_{t-1})$$

$$= \underline{-2}$$

Variansen blir även nu konstant.

Korrelationer?

/ 18

SU, STATISTIK

Skrivsal: Brunnmässalen Anonymkod: ETO-C02c Blad nr: 5

Uppgift 5

$$\hat{p}_1 = 0,8 \quad \hat{p}_2 = 0,5 \quad \hat{p}_3 = 0,4$$

a) Vi använder Yule-Walker-ekvationerna för att beräkna autokorrelationerna för en AR(3).
Då tänker jag att man skulle kunna testa om uträkningarna stämmer för en AR(1) och AR(2).

För en AR(1) ger Yule-Walker:

$$p_k = \sum_{i=1}^3 \phi_i \cdot p_{k-i} \Rightarrow \\ \hat{\phi}_1 = 0,8 = \hat{\phi}_1 \cdot 1 \Rightarrow \hat{\phi}_1 = 0,8$$

$$\hat{\phi}_2 = 0,5 = \hat{\phi}_1 \cdot 0,8 \Rightarrow \hat{\phi}_1 = 0,625$$

$$\hat{\phi}_3 = 0,4 = \hat{\phi}_1 \cdot 0,5 \Rightarrow \hat{\phi}_1 = 0,8$$

Eftersom detta är en "realization" av en stationär process och $\hat{\phi}_1 = 0,8 \neq 2 \text{ av } 3$ fall? så skulle detta kunna vara en AR(1). Om jag ställde upp det på samma sätt där antagandet är att det var en AR(2) och då efter gjorde ett ekvationssystem blev resultaten att $\hat{\phi}_1$, eller $\hat{\phi}_2$ autokor blev 0, så jag antar att detta måste vara en AR(1) (förutsatt att det är rätt övervägängssätt över huvud taget!). Np!

b) En AR(1) ges av:

$$y_t = \delta + \phi_1 y_{t-1} + \varepsilon_t \quad \varepsilon \sim (0, \sigma^2)$$

I a) antas lagat $\hat{\phi}_1 = 0,8$.

Eftersom $E(y_t) = \frac{\delta}{1-\phi_1}$ för en stationär AR(0).

börde vi kunna schatta $\hat{\delta} = E(y_t)$.
 $i = 0,8$

Längre än så kommer jag dessvärre inte...

c) $\hat{p}_4 = \sum_{i=1}^4 \hat{\phi}_i \cdot \hat{p}_3 = 0,8 \cdot 0,4 = 0,32$ ok, givet tidigare fel.
